(57) **ABSTRACT**

Embodiments of the present disclosure relate to devices and methods for treating one or more damaged, diseased, or traumatized portions of the spine, including intervertebral discs, to reduce or eliminate associated back pain. In one or more embodiments, the present disclosure relates to an expandable interbody spacer. The expandable interbody spacer may comprise a first jointed arm comprising a plurality of links pivotally coupled end to end. The expandable interbody spacer further may comprise a second jointed arm comprising a plurality of links pivotally coupled end to end. The first jointed arm and the second jointed arm may be interconnected at a proximal end of the expandable interbody spacer. The first jointed arm and the second jointed arm may be interconnected at a distal end of the expandable interbody spacer.

EXPANDABLE INTERBODY SPACER**CROSS-REFERENCE TO RELATED APPLICATIONS**

This application is a continuation-in-part application of U.S. patent application Ser. No. 13/483,852, filed on May 20, 2012, entitled Expandable Interbody Spacer, the entirety of which is incorporated herein by reference.

FIELD OF THE INVENTION

The present disclosure relates to embodiments of devices and methods for treating one or more damaged, diseased, or traumatized portions of the spine, including intervertebral discs, to reduce or eliminate associated back pain. In one or more embodiments, the present disclosure relates to an expandable interbody spacer. In addition, the present disclosure describes tools and methods for implanting the disclosed devices.

BACKGROUND OF THE INVENTION

The vertebrate spine is the axis of the skeleton providing structural support for the other body parts. In humans, the normal spine has seven cervical, twelve thoracic and five lumbar segments. The lumbar spine sits upon the sacrum, which then attaches to the pelvis, and in turn is supported by the hip and leg bones. The bony vertebral bodies of the spine are separated by intervertebral discs, which act as joints but allow known degrees of flexion, extension, lateral bending, and axial rotation.

The typical vertebra has a thick anterior bone mass called the vertebral body, with a neural (vertebral) arch that arises from the posterior surface of the vertebral body. The centra of adjacent vertebrae are supported by intervertebral discs. Each neural arch combines with the posterior surface of the vertebral body and encloses a vertebral foramen. The vertebral foramina of adjacent vertebrae are aligned to form a vertebral canal, through which the spinal sac, cord and nerve rootlets pass. The portion of the neural arch which extends posteriorly and acts to protect the spinal cord's posterior side is known as the lamina. Projecting from the posterior region of the neural arch is the spinous process.

The intervertebral disc primarily serves as a mechanical cushion permitting controlled motion between vertebral segments of the axial skeleton. The normal disc is a unique, mixed structure, comprised of three component tissues: the nucleus pulposus ("nucleus"), the annulus fibrosus ("annulus") and two vertebral end plates. The two vertebral end plates are composed of thin cartilage overlying a thin layer of hard, cortical bone which attaches to the spongy, richly vascular, cancellous bone of the vertebral body. The end plates thus act to attach adjacent vertebrae to the disc.

The spinal disc and/or vertebral bodies may be displaced or damaged due to trauma, disease, degenerative defects, or wear over an extended period of time. One result of this displacement or damage to a spinal disc or vertebral body may be chronic back pain. A common procedure for treating damage or disease of the spinal disc or vertebral body may involve partial or complete removal of an intervertebral disc. An implant, which may be referred to as an interbody spacer, can be inserted into the cavity created where the intervertebral disc was removed to help maintain height of the spine and/or restore stability to the spine. An example of an interbody spacer that has been commonly used is a cage, which typically is packed with bone and/or bone-growth-inducing mate-

2

rials. However, there are drawbacks associated with conventional interbody spacers, such as cages and other designs. For instances, conventional interbody spacers may be too large and bulky for introduction into the disc space in a minimally invasive manner, such as may be utilized in a posterior approach. Further, these conventional interbody spacers may have inadequate surface area contact with the adjacent endplates if sized for introduction into the disc space in a minimally invasive manner. In addition, conventional interbody spacers designed for introduction into the disc space in a minimally invasive manner may lack sufficient space for packing of bone-growth-inducing material, thus potentially not promoting the desired graft between the adjacent endplates.

Therefore, a need exists for an interbody spacer that can be introduced in a minimally manner that provides a desired amount of surface area contact with the adjacent endplates and has an increased space for packing of bone-growth-inducing material.

SUMMARY OF THE INVENTION

Embodiments of the present disclosure relates to an expandable interbody spacer. The expandable interbody spacer may comprise a first jointed arm comprising a plurality of links pivotally coupled end to end. The expandable interbody spacer further may comprise a second jointed arm comprising a plurality of links pivotally coupled end to end. The first jointed arm and the second jointed arm may be interconnected at a proximal end of the expandable interbody spacer. The first jointed arm and the second jointed arm may be interconnected at a distal end of the expandable interbody spacer. The first jointed arm and the second jointed arm may each be configured to fold inward in opposite directions to place the expandable interbody spacer in an expanded position.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments of the present disclosure will be more readily understood with reference to the embodiments thereof illustrated in the attached drawing figures, in which:

FIG. 1 is a top view of an expandable interbody spacer shown in a collapsed position in accordance with embodiments of the present disclosure;

FIG. 2 is a side view of the expandable interbody spacer of FIG. 1 shown in a collapsed position;

FIG. 3 is a proximal end view of the expandable interbody spacer of FIG. 1 shown in a collapsed position;

FIG. 4 is a distal end view of the expandable interbody spacer of FIG. 1 shown in a collapsed position;

FIG. 5 is an exploded view of the expandable interbody spacer of FIG. 1;

FIG. 6 is a top view of the expandable interbody spacer of FIG. 1 shown in an expanded position;

FIG. 7 is a right side view of the expandable interbody spacer of FIG. 1 shown in an expanded position;

FIG. 8 is a left side view of the expandable interbody spacer of FIG. 1 shown in an expanded position;

FIG. 9 is a proximal end view of the expandable interbody spacer of FIG. 1 shown in an expanded position;

FIG. 10 is a distal end view of the expandable interbody spacer of FIG. 1 shown in an expanded position;

FIG. 11 is a view showing disc space between adjacent vertebrae in accordance with embodiments of the present disclosure;

3

FIG. 12 is a view of a tool for insertion of an expandable interbody spacer in accordance with embodiments of the present disclosure;

FIG. 13 is a view showing the tool of FIG. 12 introducing an expandable interbody spacer into a disc space in a collapsed position in accordance with embodiments of the present disclosure;

FIG. 14 is a view showing the tool of FIG. 12 expanding an expandable interbody spacer in a disc space in accordance with embodiments of the present disclosure;

FIG. 15 is a view showing a funnel for introduction of bone-growth-inducing material into a disc space in accordance with embodiments of the present disclosure;

FIG. 16 is an exploded view of another embodiment of an expandable interbody spacer;

FIG. 17 is a top view of another embodiment of an expandable interbody spacer shown in a collapsed position;

FIG. 18 is a top view of the expandable interbody spacer of FIG. 17 shown in an expanded position;

FIG. 19 is an exploded view of the expandable interbody spacer of FIG. 17;

FIG. 20 is an exploded view of a link of a jointed arm of the expandable interbody spacer of FIG. 17;

FIG. 21 is a top view of another embodiment of an expandable interbody spacer shown in a collapsed position;

FIG. 22 is a top view of the expandable interbody spacer of FIG. 21 shown in an expanded position;

FIG. 23 is a view of the expandable interbody spacer of FIG. 21 shown in a disc space in a collapsed position;

FIG. 24 is a view of the expandable interbody spacer of FIG. 21 shown in a disc space in an expanded position;

FIG. 25 is a top view of a tool shown engaging the expandable interbody spacer of FIG. 21 in accordance with embodiments of the present disclosure;

FIG. 26 is a view showing the tool of FIG. 24 expanding the expandable interbody spacer of FIG. 24 in a disc space in accordance with embodiments of the present disclosure;

FIG. 27A is an isometric view of an exemplary expandable interbody spacer in an expanded position, in accordance with a further embodiment of the disclosure;

FIG. 27B is an isometric view of the expandable interbody spacer of FIG. 27A in the collapsed position;

FIG. 28 is an exploded view of the expandable interbody spacer of FIG. 27A.

FIG. 29 depicts a cross-sectional view of the expandable interbody spacer of FIG. 27A in the collapsed position;

FIG. 30 depicts an embodiment of an exemplary tool for implanting an embodiment of an exemplary expandable interbody spacer, in accordance with the principles of the present disclosure;

FIG. 31 depicts a partially-exploded view of various components of the tool shown in FIG. 30;

FIG. 32A depicts a cross-sectional view of a proximal portion of the tool of FIG. 30;

FIG. 32B depicts a cross-sectional view of an actuator assembly;

FIG. 32C depicts an exploded view of the actuator assembly;

FIGS. 33-43 depict various views of components of the exemplary tool of FIG. 30 and their interaction with an exemplary interbody spacer; and

FIG. 44 depicts a final implanted configuration of an exemplary embodiment of an expandable interbody spacer.

Throughout the drawing figures, it should be understood that like numerals refer to like features and structures.

DETAILED DESCRIPTION OF THE INVENTION

The preferred embodiments of the disclosure will now be described with reference to the attached drawing figures. The

4

following detailed description of the invention is not intended to be illustrative of all embodiments. In describing preferred embodiments of the present disclosure, specific terminology is employed for the sake of clarity. However, the embodiments described herein are not intended to be limited to the specific terminology so selected. It is to be understood that each specific element includes all technical equivalents that operate in a similar manner to accomplish a similar purpose.

As used herein, the term “proximal” may refer to a portion of a device or component thereof disposed closest to an operator or healthcare professional during an implantation procedure. Conversely, the term “distal” may refer to a portion of a device or component thereof disposed opposite the proximal portion and disposed farther from the operator or healthcare professional during an implantation procedure. As discussed below, the embodiments of expandable interbody spacers described herein may be implanted via any suitable approach known in the art. It is contemplated, however, that the disclosed embodiments may be implanted via an offset (e.g., 20-40 degree offset) posterior approach. Accordingly, solely for orientation purposes, a “proximal” portion of the device, when implanted, may be disposed posteriorly relative to a patient, if implanted via a posterior approach.

Referring to FIGS. 1-10, an expandable interbody spacer 10 is shown in accordance with embodiments of the present disclosure. In the illustrated embodiment, the expandable interbody spacer 10 has a proximal end 20 and a distal end 30. The expandable interbody spacer 10 may include a first jointed arm 40 and a second jointed arm 50 positioned on either side of longitudinal axis 15 of the spacer 10. The first and second jointed arms 40, 50 may be interconnected at the proximal end 20, for example, by a proximal connection member 60. The first and second jointed arms 40, 50 may be interconnected at the distal end 30, for example, by a distal connection member 70. The first and second jointed arms 40, 50 of the expandable interbody spacer 10 may be made from a number of materials, including titanium, stainless steel, titanium alloys, non-titanium alloys, polymeric materials, plastic composites, polyether ether ketone (“PEEK”) plastic material, ceramic, elastic materials, and combinations thereof. While the expandable interbody spacer 10 may be used with a posterior, anterior, lateral, or combined approach to the surgical site, the spacer 10 may be particularly suited with a posterior approach.

The first jointed arm 40 has a proximal end 80 and a distal end 90. The proximal end 80 may be pivotally coupled to the proximal connection member 60. The distal end 90 may be pivotally coupled to the distal connection member 70. Any of a variety of different fasteners may be used to pivotally couple the proximal end 80 and the distal end 90 and the proximal connection member 60 and the distal connection member 70, such as pins 100, for example. In another embodiment (not illustrated), the connection may be a hinged connection. As illustrated, the first jointed arm 40 may comprise a plurality of links that are pivotally coupled to one another. In the illustrated embodiment, the first jointed arm 40 comprises first link 110, second link 120, and third link 130. When the spacer 10 is in a collapsed position, the first link 110, second link 120, and third link may be generally axially aligned. As illustrated, the first link 110, second link 120, and third link 130 may be connected end to end. When the spacer 10 is in a collapsed position, the first link 110, second link 120, and third link 130 may be generally axially aligned. The first link 110 and the second link 120 may be pivotally coupled, and the second link 120 and the third link 130 may also be rotatably coupled. Any of a variety of different fasteners may be used to pivotally couple the links 110, 120, 130, such as pins 100, for

example. In another embodiment (not illustrated), the coupling may be via a hinged connection.

As best seen in FIGS. 1, 5-7, 9, and 10, an upper surface 140 of the first jointed arm 40 may be defined by the links 110, 120, 130. The upper surface 140 should allow for engagement of the first jointed arm 40 with one of the adjacent vertebral bodies. In some embodiments, the upper surface 140 may include texturing 150 to aid in gripping the adjacent vertebral bodies. Although not limited to the following, the texturing 150 can include teeth, ridges, friction-increasing elements, keels, or gripping or purchasing projections.

As best seen in FIGS. 7, 9, and 10 a lower surface 160 of the first jointed arm 40 may be defined by the links 110, 120, 130. The lower surface 160 should allow for engagement of the first jointed arm 40 with one of the adjacent vertebral bodies. In some embodiments, the lower surface 160 may include texturing 170 to aid in gripping the adjacent vertebral bodies. Although not limited to the following, the texturing 170 can include teeth, ridges, friction-increasing elements, keels, or gripping or purchasing projections.

The second jointed arm 50 has a proximal end 180 and a distal end 190. The proximal end 180 may be pivotally coupled to the distal connection member 70. The distal end 190 may be pivotally coupled to the distal connection member 70. Any of a variety of different fasteners may be used to pivotally couple the proximal end 180 and the distal end 190 and the proximal connection member 60 and the distal connection member 70, such as pins 100, for example. In another embodiment (not illustrated), the connection may be a hinged connection. As illustrated, the second jointed arm 50 may comprise a plurality of links that are pivotally coupled to one another. In the illustrated embodiment, the second jointed arm 50 comprises first link 200, second link 210, and third link 220. When the spacer 10 is in a collapsed position, the first link 200, second link 210, and third link 220 may be generally axially aligned. As illustrated, the first link 200, second link 210, and third link 220 may be connected end to end. The first link 200 and the second link 210 may be pivotally coupled, and the second link 210 and the third link 220 may also be pivotally coupled. Any of a variety of different fasteners may be used to pivotally couple the links 200, 210, 220, such as pins 100, for example. In another embodiment (not illustrated), the coupling may be via a hinged connection.

As best seen in FIGS. 1, 2, 6, and 8-10, an upper surface 230 of the second jointed arm 50 may be defined by the links 200, 210, 220. The upper surface 230 should allow for engagement of the second jointed arm 50 with one of the adjacent vertebral bodies. In some embodiments, the upper surface 230 may include texturing 240 to aid in gripping the adjacent vertebral bodies. Although not limited to the following, the texturing 240 can include teeth, ridges, friction-increasing elements, keels, or gripping or purchasing projections.

As best seen in FIGS. 8-10, a lower surface 250 of the second jointed arm 50 may be defined by the links 200, 210, and 220. The lower surface 250 should allow for engagement of the second jointed arm 50 with one of the adjacent vertebral bodies. In some embodiments, the lower surface 250 may include texturing 260 to aid in gripping the adjacent vertebral bodies. Although not limited to the following, the texturing 260 can include teeth, ridges, friction-increasing elements, keels, or gripping or purchasing projections.

With reference now to FIGS. 3, 5, and 9, a bore 270 extends through proximal connection end 60. The bore 270 may extend generally parallel to the longitudinal axis 12 (see FIG. 1) of the spacer 10. The first jointed arm 40 and the second jointed arm 50 may define a hollow interior portion (not

shown) that extends axially through the spacer 10. The bore 270 in the proximal connection end 60 may communicate with this hollow interior portion. As best shown on FIG. 5, the distal connection end 70 may include an opening 280. As illustrated, the opening 280 may face inward and may not extend all the way through the distal connection 70. In one embodiment, the opening 280 may be generally aligned with the bore 270 in the proximal connection end 60 such as a tool (e.g., tool 340 shown on FIG. 12) inserted into the bore 270 may be received in the opening 280 for placement of the spacer 10 into a disc space and/or expansion of the spacer 10.

FIGS. 1-4 illustrate the expandable interbody spacer 10 in a collapsed position. In accordance with present embodiments, the expandable interbody spacer 10 may be laterally expanded to an expanded position. FIGS. 6-10 illustrate the expandable interbody spacer 10 in an expanded position. In the expanded position, the first arm 40 and the second arm 50 have each been folded inward in opposite directions. For example, the proximal end 80 and the distal end 90 of the first arm 40 may be folded closer together. The links 110, 120, 130 should pivot with respect to one another when the first arm 40 is folded inward. The proximal end 80 should pivot at the proximal connection end 60, and the distal end 90 should pivot at the distal connection end 70. By way of further example, the proximal end 180 and the distal end 190 of the second arm 50 may also be folded together. The links 200, 210, 220 should pivot with respect to one another when the second arm is folded inward. The proximal end 180 should pivot at proximal connection end 60, and the distal end 190 should pivot at the distal connection end 70. After placement in the expanded position, the expandable interbody spacer 10 can be secured in the expanded position to prevent collapse of the expandable interbody spacer 10 upon application of spacer. Any of a variety of different techniques may be used to secure the expandable interbody spacer 10, including pins or other suitable locking mechanism, for example.

As illustrated by FIG. 6, the first and second jointed arms 40, 50 define an interior cavity 290 when in an expanded position. The interior cavity 290 may be filled with a bone-growth-inducing material, such as bone material, bone-growth factors, or bone morphogenic proteins. As will be appreciated by those of ordinary skill in the art, the bone-growth-inducing material should induce the growth of bone material, thus promoting fusion of the adjacent vertebra.

The expandable interbody spacer 10 may be sized to accommodate different applications, different procedures, implantation into different regions of the spine, or size of disc space. For example, the expandable interbody spacer 10 may have a width W1 (as shown on FIG. 1) prior to expansion of about 8 mm to about 22 mm and alternatively from about 10 mm to about 13 mm. By way of further example, the expandable interbody spacer 10 may be expanded to a width W2 (as shown on FIG. 6) in a range of about 26 mm to about 42 mm and alternatively from about 16 mm to about 32 mm. It should be understood that the width W1 or W2 whether prior to, or after, expansion generally refers to the width of the expandable interbody spacer 10 extending transverse to the longitudinal axis 12 of the spacer 10. In general, the width W2 of the expandable interbody spacer 10 after expansion should be greater than the width W1 of the expandable interbody spacer 10 prior to expansion.

In accordance with present embodiments, the expandable interbody spacer 10 may be used in the treatment of damage or disease of the vertebral column. In one embodiment, the expandable interbody spacer 10 may be inserted into a disc space between adjacent vertebrae in which the intervertebral disc has been partially or completely removed. FIG. 11 illus-

7

trates a spinal segment 300 into which the expandable interbody spacer 10 (e.g., FIGS. 1-10) may be inserted. The spinal segment 300 includes adjacent vertebrae, identified by reference numbers 310 and 320. Each of the adjacent vertebrae 310, 320 has a corresponding endplate 315, 325. The disc space 330 is the space between the adjacent vertebrae 310, 320. FIG. 12 illustrates a tool 340 that may be used in the insertion of the expandable interbody spacer 10 into the disc space 330. The tool 340 includes a shaft 350 having an elongated end portion 360 for coupling to the expandable interbody spacer 10. The elongated end portion 360 has a distal tip 370.

FIGS. 13 and 14 illustrate introduction of an expandable interbody spacer 10 into the disc space 330 using tool 340. For illustrative purposes, the upper vertebra 330 shown on FIG. 11 has been removed from FIGS. 13 and 14. As illustrated, the spacer 10 may be secured to the tool 340. For example, the elongated end portion 360 of the tool 340 may be disposed through the bore 270 (e.g., see FIG. 5) in the proximal connection end 60 with the distal tip 370 (e.g., see FIG. 12) of the end portion 360 secured in the opening 280 (e.g., see FIG. 5) in the distal connection end 70. As illustrated by FIG. 13, the tool 340 may introduce the spacer 10 into the disc space 330 through an access cannula 380. After introduction into the disc space 330, the spacer 10 may be laterally expanded. In accordance with present embodiments, the spacer 10 can be laterally expanded by folding the first arm 40 and the second arm 50 inward. By expanding laterally, the spacer 10 has an increased surface area contact with the endplate 325. In addition, the spacer 10 may engage harder bone around the apophyseal ring. As previously mentioned, an interior cavity 290 should be formed in the spacer 10 when in the expanded position. The tool 340 may then be detached from the spacer 10 and removed from the cannula 380. As illustrated by FIG. 15, a funnel 390 may then be placed on the cannula 380. Bone-growth inducing material may then be placed into the interior cavity 290 through the cannula 380. Because the spacer 10 has been laterally expanded, the interior cavity 290 should have a desirable amount of space for packing of the bone-growth-inducing material.

FIG. 16 illustrates an expandable interbody spacer 10 in accordance with an alternative embodiment. In the illustrated embodiment, the expandable interbody spacer 10 comprises a first jointed arm 40 and a second jointed arm 50. The first jointed arm 40 has a proximal end 80 and a distal end 90. The first jointed arm 40 comprises a plurality of links 110, 120, 130 connected end to end, for example, by pins 100. The first jointed arm 40 further may comprise washers 105 (e.g., PEEK washers) that may be disposed between the links 110, 120, 130 at their connections. The second jointed arm 50 has a proximal end 180 and a distal end 190. The second jointed arm 50 comprises a plurality of links 200, 210, 220 connected end to end, for example, by pins 100. The second jointed arm 50 further may comprise washers 105 (e.g., PEEK washers) that may be disposed between the links 200, 210, 220 at their connections. Washers 105 may also be disposed between the first arm 40 and the proximal connection member 60 and the distal connection member 70 at their respective connections. Washers 105 may also be disposed between the second arm 50 and the proximal connection member 60 and the distal connection member 70 at their respective connections. The washers 105 should have an interference fit to cause friction such that the spacer 10 may hold its shape in the entire range of the expanded implant.

The proximal ends 80, 180 may be pivotally coupled, for example, by pin 100, as shown on FIG. 19. The distal ends 90, 180 may also be pivotally coupled, for example, by pin 100,

8

as shown on FIG. 19. The first jointed arm 40 comprises first link 110 and third link 130, the first link 110 and the third link 130 being pivotally coupled. In contrast to the first jointed arm 40 of FIGS. 1-10, there

Referring now to FIGS. 17-19, an expandable interbody spacer 10 is illustrated in accordance with another embodiment of the present disclosure. In the illustrated embodiment, the expandable interbody spacer 10 comprises a first jointed arm 40 and a second jointed arm 50. The first jointed arm 40 has a proximal end 80 and a distal end 90. The second jointed arm 50 has a proximal end 180 and a distal end 190. The proximal ends 80, 180 may be pivotally coupled, for example, by pin 100, as shown on FIG. 19. The distal ends 90, 180 may also be pivotally coupled, for example, by pin 100, as shown on FIG. 19. The first jointed arm 40 comprises first link 110 and third link 130, the first link 110 and the third link 130 being pivotally coupled. In contrast to the first jointed arm 40 of FIGS. 1-10, there is no second link 120. As shown by FIG. 20, the third link 130 may comprise a first link segment 400 and a second link segment 410, which may be secured to one another by pins 420, for example. First link segment 400 and second link segment 410 may also have a tongue-and-groove connection, for example a groove 430 in the first link segment 400 may receive a tongue 440 of the second link segment 410. The second jointed arm comprises first link 200 and third link 220, the first link 200 and the third link 220 being pivotally coupled. In contrast to the second joint arm 50 of FIGS. 1-10, there is no second link 210.

In accordance with present embodiments, lateral expansion of the expandable interbody spacer 10 of FIGS. 17-19 may include folding the first arm 40 and the second arm 50 inward. For example, the proximal end 80 and the distal end 90 of the first arm 40 may be folded together, and the proximal end 180 and the distal end 190 of the second arm 50 may also be folded together.

Referring now to FIGS. 21 and 22, an expandable interbody spacer 10 is illustrated in accordance with another embodiment of the present disclosure. In the illustrated embodiment, the expandable interbody spacer 10 has a proximal end 20 and a distal end 30. The expandable interbody spacer 10 may include a first jointed arm 40 and a second jointed arm 50 positioned on either side of longitudinal axis 12 of the spacer 10. As illustrated, the expandable interbody spacer 10 further may comprise an internal screw 450. The internal screw 450 may comprise a head 460 and an elongated body 470, which may extend generally parallel to the longitudinal axis 12 of the spacer 10. In some embodiments, the internal screw 450 may extend from the proximal end 20 to the distal end 30 of the spacer 10. In one embodiment, the elongated body 470 may be retractable. For example, the elongated body 470 may retract into the head 460, as shown on FIG. 22.

As illustrated by FIGS. 23 and 24, the spacer 10 may be introduced into the disc space 330, wherein the spacer 10 can be laterally expanded. In accordance with present embodiments, the spacer 10 can be laterally expanded by folding the first arm 40 and the second arm 50 inward. In some embodiments, the elongated body 470 may be retracted into the head 460 to cause folding of the first arm 40 and the second arm 50 inward, as the first arm 40 and the second arm 50 are secured to the distal end 480 of the internal screw 450.

FIG. 25 shows attachment of a tool 490 to the expandable interbody spacer 10 of FIGS. 22 and 23 in accordance with embodiments of the present disclosure. As illustrated, the tool 490 may have an attachment end 500, which can be secured to the head 460 of the internal screw 450. As shown by FIG. 26,

the tool 40 can be used to introduce the spacer 10 into the disc space 330, wherein the spacer 10 can be laterally expanded.

Turning now to FIG. 27A-29, there are depicted multiple views of a further embodiment of an expandable interbody spacer 2700, in accordance with an aspect of the present disclosure. The expandable interbody spacer 2700 may include one or more features of any of the other interbody spacers discussed herein. For example, although the spacer 2700 and its components may be made of titanium, any suitable biocompatible material known in the art may be used.

With reference to FIG. 27A, for example, spacer 2700 may include, among other things, a proximal portion 2702. Proximal portion 2702 may include a substantially cylindrical portion 2703. Cylindrical portion 2703 may include a complete cylindrical shape or a partial cylindrical shape. In addition, cylindrical portion 2703 may define a lumen 2704 therethrough. A surface of the lumen 2704 may include one or more geometric features, such as, for example, screw threads 2705, as described in greater detail below. In one embodiment, lateral surfaces of cylindrical portion 2703 may include one or more geometric features 2706 to facilitate engagement by a tool 3000, as discussed below in greater detail. The geometric features 2706 may include any suitable shape and/or configuration. In one embodiment, the geometric features 2706 may include elongate notches disposed in the side walls that define cylindrical portion 2703. Further, the elongate notches may extend into the side walls in a direction that is substantially perpendicular.

A plurality of cantilevered ledges 2707 may extend distally from a distal portion of cylindrical portion 2703. Aside from being disposed in an opposing relation to one another, the cantilevered ledges 2707 may be substantially similar to one another. The ledges 2707 may include any suitable configuration, shape, and/or size known in the art. In one embodiment, the ledges 2707 may define a space 2708 therebetween for receiving a plurality of links (as described below) of spacer 2700. External surfaces (e.g., inferior and superior surfaces) of ledges 2707 may include texturing 150 to aid in gripping adjacent vertebral bodies, as described herein. The external surfaces may also be configured to promote bone ingrowth. For example, in one embodiment, the external surfaces of ledges 2707 may include a porous configuration or may include a coating of, e.g., hydroxyapatite. External edges of ledges 2707 may include any suitable configuration for matingly coupling with corresponding portions of the plurality of links discussed below. In one embodiment, the external edges of ledges 2707 may be curved to facilitate the plurality of links pivoting relative to each of ledges 2707. Further, each of ledges 2707 may include one or more openings 2707a for receiving a pivot pin 2709 therethrough, as described below in greater detail.

With continued reference to FIGS. 27A-29, proximal portion 2702 may be rotatably coupled via a plurality of pivot pins 2709 to links 2710 and 2712. Links 2710 and 2712 may be substantially similar to one another. Indeed, as depicted in, e.g., FIG. 27A, links 2710 and 2712 may be positioned as mirror images of each other. Thus, for the purposes of brevity, similar portions of links 2710 and 2712 will be described together. Proximal portions 2714 of links 2710 and 2712 may be received in space 2708. The proximal portions 2714 of links 2710, 2712 may be appropriately configured and dimensioned to fit between ledges 2707. In addition, each of proximal portions 2714 includes a through-hole 2716 for receiving a pivot pin 2709. The through-hole 2716 may be disposed in a scalloped cut-out on proximal portions 2714 of each of links 2710, 2712.

Pivot pin 2709 may include any suitable fastener known in the art for movably coupling links 2710 and 2712 to proximal portion 2702. In one embodiment, pivot pin 2709 may be inserted and retained within openings 2707a and through-holes 2716 via an interference or friction fit.

In some embodiments, an interface between one or both of links 2710 and 2712 and proximal portion 2702 may be configured to retain one or both of links 2710 and 2712 in a predetermined position relative to proximal portion 2702. For example, an edge of ledge 2707 may interact with a wall 2717 to frictionally retain in a predetermined position relative to proximal portion 2702. In one embodiment, the wall 2717 may include a raised portion (not shown), such as, e.g., a rounded bump, or other suitable feature against which the edge of ledge 2707 may engage.

Superior and inferior surfaces of links 2710 and 2712 may also include suitable texturing 150 as described above. In addition, the superior and inferior surfaces may be configured to promote bone ingrowth, as described above. Each link 2710 and 2712 also may define one more openings 2718 therethrough. The openings 2718 may include any suitable configuration known in the art. In one embodiment, openings 2718 may include a substantially rectangular configuration. In other embodiments, openings 2718 may include other shapes. In one embodiment, the openings 2718 may be disposed distally of wall 2717. Openings 2718 may be configured as bone graft windows, allowing facilitating bone ingrowth into an interior of spacer 2700 through openings 2718. An edge of opening 2718 may be appropriately beveled, chamfered, and/or rounded, as is known in the art. Further, opening 2718 may be generally disposed in a central portion of each of links 2710 and 2712.

A distal end portion of links 2710, 2712 may be configured to be movably coupled to another link, as discussed herein. In one embodiment, the distal end portions of links 2710, 2712 may define a male hinge 2719 that includes a hole 2720 therethrough. The hole 2720 may be configured to receive a pivot pin 2709 for rotatable coupling the links 2710, 2712 to adjacent links described below. In one embodiment, a wall perpendicular to hinge 2719 may define one or more position retaining features 2721. As will be described below, the position retaining features 2721 may be configured to interact with corresponding features on an adjacent link to frictionally retain links in a predetermined position.

The ends of each of links 2710, 2712 that are opposite to the ends coupled to proximal portion 2702 may be movably coupled to links 2722 and 2724. Each of links 2722 and 2724 may be substantially similar to one another. Thus, those of ordinary skill in the art will understand that either link 2722 or link 2724 may include features of the other link 2722 or link 2724. A proximal end portion of each of links 2722 and 2724 may define a recess 2725 for receiving hinge 2719. The recess 2725 may be disposed between a pair of proximally extending arms 2725a and 2725b. Each of arms 2725a, 2725b may be substantially similar to one another and, thus, for the purposes of efficiency, only one arm 2725a will be discussed.

Arm 2725a may include any suitable shape and configuration known in the art. In one embodiment, an external surface of arm 2725a may be rounded to facilitate rotating relative to link 2712 or 2710. A lateral surface of arm 2725a may include one or more position retaining features 2727 for engaging position retaining features 2721. In use, as links 2724 and 2712 may rotate relative to one another, for example, position retaining features 2721 and 2727 may frictionally engage one another to retain links 2724 and 2712 in a desired position. Position retaining features 2727 may be similar to position retaining features 2721. For example, in

11

one embodiment, position retaining feature 2727 may be a bump that is raised relative to a remaining surface of arm 2725a.

Each link 2722 and 2724 may also include one or more openings 2718 disposed generally in a central portion of links 2722 and 2724. As discussed above, openings 2718 may be configured to extend through each respective link 2722, 2724, and may be configured to facilitate bone-ingrowth. One or more edges of openings 2718 may be beveled, rounded, and/or chamfered as known in the art.

A distal end of each link 2722 and 2724 may include a plurality of extensions 2729, 2730. Extensions 2729, 2730 may be configured to extend away from a central portion of the links 2722, 2724, and may be configured to define a space 2732 therebetween. The space 2732 may be configured to receive a distal component of spacer 2700. Each of extensions 2729, 2730 may include a through-hole 2734 therein. The through-hole 2734 may include any suitable configuration known in the art. The through-hole 2734 may be configured to receive a respective pivot pin 2709 for movably coupling links 2722, 2724 to the distal component discussed in greater detail below.

Inward facing surfaces of one or both of extensions 2729, 2730 may be configured to interact or engage with corresponding surfaces of the extensions 2729, 2730 of an opposing link. For example, as shown in FIG. 28, the inward facing surfaces of extensions 2729, 2730 of one of links 2722, 2724 may include a plurality of teeth, recesses, protrusions, notches, or the like, that may be configured to engage corresponding geometry disposed on the inward facing surfaces of the extensions disposed on the other of links 2722, 2724. In the preferred embodiment, the inward facing surfaces of extensions 2729, 2730 may include a plurality of gear teeth 2736. The gear teeth 2736 of each extension 2729, 2730 may engage gear teeth 2736 of the opposing link to facilitate rotating one link relative to the other in a single plane.

Each of links 2722 and 2724 may be movably coupled to a distal component 2740. Distal component 2740 may include a substantially trapezoidal configuration. That is, distal component 2740 may taper in the distal direction from a larger width dimension to a smaller width dimension. With reference to FIG. 28, a proximal face of distal component 2740 may include an opening 2742 in communication with a hole 2744 through distal component 2740. As shown in, e.g., FIG. 27A, hole 2744 extends completely through distal component 2740. Hole 2744 may include any suitable configuration known in the art. In one embodiment, hole 2744 may include a substantially conical configuration as it tapers towards a smaller diameter in its distal portion. As will be discussed below, hole 2744 may include internal threads for engaging with an implantation tool.

Superior and inferior surfaces of distal component 2740 may be configured to receive extensions 2729, 2730. Accordingly, as best shown in FIG. 28, for example, these surfaces may include a stepped portion 2746 for receiving extensions 2729, 2730 of each link 2722, 2724. Stepped portion 2746 may include a plurality of openings 2748 for receiving a pivot pin 2709 therein to rotatably couple the links 2722, 2724 to distal component 2740. Those of ordinary skill in the art will understand that links 2722, 2724 may be coupled to distal component 2740 by any suitable means known in the art. Distal component 2740 may include a raised portion disposed distally of stepped portion 2746. The raised portion 2750 may include any suitable configuration known in the art. In one embodiment, the raised portion 2750 may include a distally

12

tapering configuration, as shown in FIG. 27A. As also shown in FIG. 27A, distal component 2740 may include a curved external configuration.

With reference now to FIGS. 28-29, the spacer 2700 may be maintained in an expanded configuration (shown in FIG. 27A) by any suitable mechanism known in the art. As discussed above, the spacer 2700 may include certain position retaining features. To more permanently retain an expanded configuration of spacer 2700, the spacer 2700 may include a locking feature 2760. Those of ordinary skill in the art will understand that locking feature 2760 may include any suitable configuration known in the art. In one embodiment, locking feature 2760 may include a substantially cylindrical configuration. In addition, locking feature 2760 may define a lumen 2762 therethrough. In one embodiment, the walls of the lumen 2762 may include a plurality of geometric configurations 2762a to allow a tool (described in greater detail below) to engage and rotate locking feature 2760. Further, locking feature 2760 may be configured and dimensioned to be received within lumen 2704 of proximal portion 2702, as shown in FIG. 29. In one embodiment, an external surface of locking feature 2760 may include suitable geometric features for engaging lumen 2704. In the embodiment where lumen 2704 includes threads 2705, the external surface of locking feature 2760 may include corresponding threads 2764. The threads 2705 in lumen 2704 and threads 2764 may cooperate to only allow locking feature 2760 to be advanced into lumen 2704 without being withdrawn, regardless of whether locking feature is rotated clockwise or counter-clockwise. For example, in one embodiment, threads 2705 may terminate short of the opening to lumen 2704. In addition, or alternatively, one or more raised circumferential or partially circumferential protrusions 2705a may be formed just inside of the opening to lumen 2704. In such embodiments, locking feature 2760 may be pre-disposed within lumen 2704 during a manufacturing or assembly process and before delivery to a user or healthcare professional. Thus, the user or healthcare professional is only able to rotate locking feature 2762 to advance it further into lumen 2704 and is unable to remove locking feature 2762 from 2704.

With reference to FIG. 29, and as will be discussed in greater detail below, locking feature 2760 may be configured to be advanced into lumen 2704 and protrude out of cylindrical portion 2703 into space 2708, which, as shown in FIG. 29, is occupied by proximal portions 2714 of links 2710 and 2712 when the spacer 2700 is in the collapsed configuration. When the spacer 2700 is in the expanded position, the proximal portions 2714 may be moved out of the space 2708. Accordingly, locking feature 2760 may be rotated and consequently advanced further into lumen 2704 so that a distal portion of locking feature 2760 extends out of lumen 2708 and into the space 2704. In this position, the locking feature 2762 may be configured to prevent links 2710 and 2712 from returning to their collapsed positions.

The components of spacer 2700 may be fabricated from any suitable material known in the art, including, but not limited to those described above. In one embodiment, one or more components of spacer 2700 may be fabricated from titanium. Further, portions of spacer 2700 may include any suitable coating known in the art, including, but not limited to, coatings of suitable therapeutic, antiseptic, anesthetic, and/or antibiotic. In addition, as alluded to above, portions of spacer 2700 may be configured to promote bone ingrowth into the structure of spacer 2700.

Turning now to FIGS. 30-31, there is depicted an exemplary embodiment of a tool 3000 for effecting implantation, removal, and otherwise manipulation of the various embodi-

13

ments of expandable interbody spacers described herein. Tool **3000** may include a plurality of components, each of which will be discussed in greater detail below. Those of ordinary skill in the art will recognize that any of the individual components discussed herein may be combined with other components or may be omitted altogether without departing from the principles of the present disclosure.

Tool **3000** may include a handle assembly **3001**. Handle assembly may include an elongate structure **3002** configured to be held in the hand of an operator or healthcare professional. As such, the elongate structure **3002** may be appropriately configured and dimensioned as is known in the art. In some embodiments, elongate structure **3002** may include a plurality of geometric configurations or features **3004**, such as, e.g., bumps, grooves, indentations, ridges, knobs, cut-outs, etc. for gripping by an operator. In addition, elongate structure **3002** may include a constant cross-sectional dimension throughout its length, or elongate structure **3002** may include varying dimensions throughout its length. Further, elongate structure **3002** may include a substantially circular cross-sectional configuration. In some embodiments, however, elongate structure **3002** may include any suitable cross-sectional configuration, including, but not limited to, square, rectangular, triangular, etc.

A generally cylindrical extension member **3006** may extend away from a superior surface **3005**. For the purposes of FIGS. **30-31** only, the orientation depicted is presumed to be an orientation during operation. Thus, terms such as “superior,” “anterior,” “proximal,” “distal,” “inferior,” and “posterior” are used relative to this orientation. The extension member **3006** may serve to rotatably connect elongate structure **3002** to holder **3008**.

Holder **3008** may include any suitable configuration known in the art. In one embodiment, holder **3008** may be configured, shaped, and sized to receive and frictionally engage a proximal portion of an inserter fork described in greater detail below. In one embodiment, for example, holder **3008** may include a substantially U-shaped configuration. The inserter fork may be received with the “U” portion **3008a** of the holder **3008**. The U-shaped holder **3008** may include a base portion, and two superiorly extending arms **3009**. One or more of arms **3009** may be provided with one or more geometric features for frictionally engaging and retaining the inserter fork. For example, the geometric features may include dents, indents, recesses, apertures, protrusions, ribs, and the like. In one embodiment, an inner surface of an upper portion of each arm **3009** may include a rib **3010**. In some embodiments, the U-shaped holder **3008** may include a securing member for retaining (by, e.g., friction) the inserter fork within holder **3008**. In one embodiment, the securing member may be selectively actuatable. For example, the base portion of the holder **3008** may include a set screw (not shown) or other similar mechanism that may selectively engage a portion of the inserter fork to retain the inserter fork relative to the holder **3008**. The set screw may be configured to transition between a first configuration and a second configuration. In the first configuration, the set screw may be received substantially completely or completely within the base portion of holder **3008**. In the second configuration, the set screw may be advanced out of the base portion **3008** and into the “U” portion **3008a**. The set screw may be configured to transition between the first and second configurations by rotating elongate structure **3002** relative to holder **3008** in the directions shown by arrow A. For example, rotating elongate structure **3002** may rotate a head (not shown) of the set screw, thereby advancing the set screw out of the base portion of holder **3008**.

14

With continued reference to FIG. **31**, the inserter fork may include a generally elongate structure **3012**. In some embodiments, the elongate structure **3012** may define one or more lumens therein. For example, as shown in FIG. **32A**, the elongate structure **3012** may define a lumen **3014** there-through. Elongate structure **3012** may include any suitable cross-sectional structure known in the art. For example, in some embodiments, the elongate structure **3012** may be a generally tubular structure. In other embodiments, elongate structure **3012** may include a substantially rectangular cross-sectional configuration. In a further embodiment, the cross-sectional configuration of elongate structure **3012** may vary along its length. For example, as shown in FIG. **31**, a distal portion of elongate structure **3012** may include a substantially square or rectangular cross-sectional configuration and a proximal portion of elongate structure **3012** may include a substantially circular cross-sectional configuration.

With reference to FIGS. **31** and **33**, a distal portion of elongate structure **3012** may be configured in a fork-like configuration. More particularly, a distal portion of elongate structure **3012** may include a vertical slit **3016** defining two arms **3018** and **3020**. Although only two arms **3018**, **3020** are shown, those of ordinary skill in the art will understand that a greater or lesser number of arms may be contemplated in accordance with the principles of the present disclosure. For example, the distal portion of elongate structure **3012** may include only a single arm. Alternatively, elongate structure **3012** may include two longitudinal slits disposed in perpendicular planes, thereby creating four arms (not shown). As a result of one or more of the configuration of the elongate structure **3012**, the configuration of slit **3016**, and the material properties of elongate structure **3012**, the arms **3018** and **3020** may exhibit resiliency or other spring-like characteristics. For example, the arms **3018** and **3020** may be biased away from one another. In another embodiment, the arms **3018** and **3020** may be biased toward one another.

The arms **3018** and **3020** may be substantially similar to one another. Accordingly, for the purposes of efficiency, only the features of arm **3020** will be described. Those of ordinary skill will understand that arm **3018** may include one or more features of arm **3020**. With specific reference to FIG. **33**, a distal end **3022** of arm **3020** may be configured to releasably engage proximal portion **2702** of spacer **2700** via features **2706**. More particularly, the distal end **3022** of arm **3020** may include a projection **3024** configured and shaped to be received within feature **2706**. For example, as shown in FIG. **33**, projections **3024** may be configured to extend towards each other. In some embodiments, feature **2706** may include a projection, and the distal end **3022** of arm **3020** may include a notch or other recess for releasably engaging the projection. Furthermore, a distal end portion of arm **3020** proximate to projections **3024** may include one or more geometric features configured for assisting in urging arm **3020** towards arm **3018** and vice versa. More particularly, an external surface of arm **3020** may include a rib **3026**, which may be engaged by sleeve **3030** to urge arm **3020** toward arm **3018**. The rib **3026** may include any suitable configuration known in the art. For example, in one embodiment, the rib may extend generally transverse to a longitudinal axis of the elongate structure **3012**. In some embodiments, a proximal portion of rib **3026** may be configured to transition smoothly to an external surface of the remainder of arm **3020**. That is, a proximal portion of rib **3026** may include a tapering or a generally ramp-like configuration. Further, although only one rib **3026** is depicted on arm **3020**, those of ordinary skill will understand that any suitable number of ribs **3026** may be provided. Furthermore, the rib **3026** may include a height dimension that correlates to

15

an amount of travel needed to move arm **3020** toward arm **3018** (and vice versa) so as to effectively engage spacer **2700**.

With renewed reference to FIGS. **31** and **32A-B**, a proximal end portion **3013** of elongate structure **3012** may be configured as follows. In one embodiment, the proximal end portion **3013** may include a horizontal slit **3028**, which may extend from the proximal end of elongate structure **3012** distally to a position just proximal of knob **3032** on elongate structure **3012**. The slit **3028** may define two arms **3028a**, **3028b**, which may be configured to be either biased away or toward one another. A proximal end of each arm **3028a**, **3028b** may be configured to assist securing the inserter fork to an actuator assembly, which will be discussed in greater detail below. In an embodiment, the proximal end of at least one of arms **3028a**, **3028b** may include a raised flange **3027**.

As alluded to above, elongate structure **3012** may include a knob **3032** disposed thereon. Knob **3032** may include any suitable configuration. In one embodiment, knob **3032** may be disposed distally of slit **3028**. An outer surface of knob **3032** may include suitable geometric features for securing knob **3032** within holder **3008**. For example, an outer surface of knob **3032** may include a plurality of knurls, indents, recesses, and/or projections thereon. In one embodiment, knob **3032** may include a plurality of channels **3031** disposed thereon. The channels **3031** may be configured to receive at least one of ribs **3010** to facilitate securing knob **3032** with holder **3008**. In some embodiments, elongate structure **3012** may include a mechanism for limiting longitudinal movement of elongate structure **3012** relative to holder **3008**. For example, elongate structure **3012** may include a radially extending flange **3033** configured to abut one of arms **3009** or the base portion of U-shaped holder **3008** so as to prevent elongate structure **3012** from moving proximally relative to handle **3001**. Furthermore, elongate structure **3012** may include a plurality of screw threads **3029** disposed on an external surface thereof. In one embodiment, the threads **3029** may be disposed proximally of slit **3016** but distally of flange **3033**. As shown in FIG. **31**, threads **3029** may be disposed substantially closer to flange **3033** than slit **3016**.

Elongate structure **3012** may be configured to be received within a lumen **3030a** of sleeve **3030**. Sleeve **3030** may include any suitable configuration known in the art. For example, sleeve **3030** generally may include a configuration corresponding to an outer periphery of elongate structure **3012**. More particularly, sleeve **3030** may include a distal portion having a substantially rectangular cross-sectional configuration, and a proximal portion having a substantially circular cross-sectional configuration. The lumen **3030a** within sleeve **3030** may be similarly configured. That is, lumen **3030a** may include a configuration that corresponds to an outer periphery of elongate structure **3012**. That is, lumen **3030a** may include a distal portion having a substantially rectangular cross-sectional configuration, and a proximal portion having a substantially circular cross-sectional configuration. A proximal portion of lumen **3030a** may include a width dimension larger than a similar width dimension at a distal portion of lumen **3030a**. In addition, a distal end of lumen **3030a** may be configured to urge arms **3018** and **3020** towards one another so that they may engage spacer **2700**, as discussed herein. Further, in one embodiment, sleeve **3030** may be a substantially elongate hollow member having a neck portion **3034** and a proximal lip **3036** at a proximal end thereof. Instead of lip **3036**, those of ordinary skill in the art will understand that any suitable geometric configuration may be used within the principles of the present disclosure.

Prior to being received over elongate structure **3012**, a proximal portion of sleeve **3030** may be operably coupled to

16

an inserter knob **3038**. Inserter knob **3038** may be any suitable knob known in the art and may include any suitable configuration. In one embodiment, knob **3038** may include a generally cylindrical configuration. However, any suitable configuration may be used in accordance with the principles of the present disclosure. Knob **3038** may include at least one lumen **3040**. Lumen **3040** may extend completely through knob **3038** or partially therethrough. A distal portion of an inner surface of lumen **3040** may include at least one geometric feature **3042** for interacting with lip **3036** so as to retain inserter knob **3038** on sleeve **3030**. In one embodiment, geometric feature **3042** may include a circumferential channel configured to receive lip **3036** therein. With reference now to FIG. **32A**, lumen **3040** may include a plurality of screw threads **3044** for cooperating with threads **3029** on elongate structure **3012**. Although the depicted embodiment illustrates that screw threads **3044** are disposed at a proximal portion of lumen **3040**, threads **3044** may be disposed along any portion of lumen **3040**. For example, in one embodiment, threads **3044** may extend from a midpoint of lumen **3040** to a proximal end thereof.

With reference now to FIGS. **31-32C**, actuator assembly **3050** will be described. Actuator assembly **3050** may include a plurality of components operably coupled together and operable to facilitate expanding spacer **2700**, as discussed below in greater detail. Although the plurality of components are described individually, those of ordinary skill in the art will appreciate that any of the described components may be combined with one or more of the other components and/or eliminated altogether without departing from the principles of the present disclosure.

Actuator assembly **3050** may include a central portion **3052**, which may include a proximal head **3054** and an elongate tubular member **3056** extending therefrom. Central portion **3052** may define a lumen **3058**. Lumen **3058** may extend completely through central portion **3052**. Lumen **3058** may include any suitable configuration known in the art. For example, as shown, lumen **3058** may include a substantially circular cross-sectional configuration. In one embodiment, proximal end **3054** may include a channel **3060** for receiving a locking tab **3062** therein, which will be discussed in greater detail below. Channel **3060** may include any suitable configuration, and may be dimensioned and shaped to correspond to locking tab **3062**. Further, channel **3060** may be configured to cut through lumen **3058**, as shown in FIG. **32B**. In addition, a portion of lumen **3058** may include a plurality of screw threads **3064**. The screw threads **3064** may be disposed along any portion of lumen **3058**. For example, in the depicted embodiment, screw threads **3064** may be disposed along only a proximal portion of lumen **3058**. Screw threads **3064** may be disposed in lumen **3058** on either side of channel **3060**. The screw threads **3064** may extend until a proximalmost end of lumen **3058**.

Externally, proximal head **3054** may include any suitable configuration. In the depicted embodiment, for example, proximal head **3054** may include a substantially planar proximal end face **3066**. The end face **3066** may include an opening **3067** in communication with lumen **3058**. In addition, end face **3066** may include a second opening **3068** for receiving a retention pin **3069** therein. Opening **3068** include a diameter that is smaller than opening **3067**. As will be discussed below, retention pin **3067** may be disposed in opening **3068** for retaining tab **3062** in channel **3060**. Proximal head **3054** may include a generally circular cross-sectional configuration. In one embodiment, however, proximal head **3054** may include substantially planar superior **3070** and inferior (not shown) surfaces. As depicted in FIG. **32C**, planar superior surface

17

3070 may include an opening **3071** in communication with channel **3060** for receiving tab **3062** therein. With continued reference to FIGS. **32B-32C**, central portion **3052** may include any suitable external configuration known in the art. In one embodiment, central portion **3052** may include a substantially uniform external configuration. In the depicted embodiment, central portion **3052** may include a step **3072**. Step **3072** may be located at any portion along a length of central portion **3052**. In one embodiment, step **3072** may be located at a midpoint of central portion **3052**. Step **3052** may include any suitable configuration. For example, step **3052** may be the interface between a relatively smaller diameter distal portion **3052a** of central portion **3052** and a relatively larger diameter proximal portion **3052b** of central portion **3052**. As shown in, e.g., FIG. **32C**, step **3072** may include a ramped surface in some embodiments. Further, a portion of proximal portion **3052b** may be configured to receive sleeve member **3076** thereon. Accordingly, proximal portion **3052b** may include one or more suitable geometric configurations, such as, e.g., screw threads **3074**, for cooperating with corresponding screw threads **3077** within sleeve member **3076**, as described in greater detail below. Screw threads **3074** may extend along any portion of proximal portion **3052b**. For example, screw threads **3074** may extend along a substantial entirety of proximal portion **3052b** or only for a portion thereof.

Distal portion **3052** may be configured, sized, and dimensioned to be received within a lumen defined by arms **3028a** and **3028b**. In one embodiment, distal portion **3052** may include a diameter (or if not tubular, a width dimension) that is larger than a diameter (or width dimension) of the lumen defined by arms **3028a**, **3028b**, so as to spread apart arms **3028a**, **3028b** when distal portion **3052** is received therebetween. In this manner, distal portion **3052** may be frictionally retained by the inherent resilient properties of arms **3028a**, **3028b** acting on distal portion **3052**. To facilitate with orientation and guiding distal portion **3052** into the lumen defined by arms **3028a**, **3028b**, distal portion **3052** may include one or more projections **3075**, which may be configured to be slidably received within slit **3028**.

As noted above, opening **3071** and channel **3060** may be configured to receive therein a locking tab **3062** for receiving a tool within lumen **3058** of actuator **3050**. Tab **3062** may include any suitable configuration known in the art. In one embodiment, tab **3062** may be resiliently biased in a direction out of channel **3060** by one or more springs or spring like members **3063**. Further, tab **3062** may be retained in channel **3060** by retention pin **3069**, described above. Tab **3062** may further define a passageway **3062a** therethrough. Passageway **3062a** may include any configuration known in the art. As discussed below, passageway **3062a** may be configured (e.g., may include one or more projections) to engage channel **3206** of threaded shaft **3200** for retaining threaded shaft within actuator assembly **3050**.

Sleeve **3076** may include a generally cylindrical member defining a lumen **3078** therethrough. Sleeve **3076** may include any suitable configuration known in the art. In one embodiment, sleeve **3076** may include a generally circular cross-sectional configuration. However, sleeve **3076** may include any suitable cross-sectional configuration. Further, a distal end of sleeve **3076** may include a generally tapered configuration. Lumen **3078** may include a generally circular cross-sectional configuration, and may be configured to receive proximal portion **3052b** therein. Indeed, as alluded to above, lumen **3078** may include a plurality of threads **3077** configured to mate with threads **3074** to retain sleeve **3076** on central portion **3052**. Threads **3077** may extend along any

18

suitable portion of lumen **3078**. In one embodiment, for example, threads may extend an entirety of lumen **3078**. In another embodiment, threads **3077** may extend along only a portion of lumen **3078**.

An overall maximum diameter of sleeve **3076** may be less than a diameter or width of proximal head **3054**. In addition, sleeve **3076** may include a step **3079** that defines an interface between a relatively larger diameter distal portion **3076b** of sleeve **3076** and relatively smaller diameter proximal portion **3076a** of sleeve **3076**. Step **3079** may be disposed at any suitable location along sleeve **3076**. Further, sleeve **3076** may include one or more longitudinal grooves **3080** extending distally from a proximal end thereof. The grooves **3080** may be configured to receive rods **3081** therein, which may be configured to prevent sleeve **3076** from rotating within housing **3090** of actuator **3050**, as described below in greater detail.

A washer **3082** may be configured to be frictionally retained on proximal portion **3076a**, as shown in FIG. **32B**. Washer **3082** may include a generally cylindrical structure that defines a lumen **3084** therethrough. In addition, washer **3082** may define a proximal ledge **3085** configured to abut a distal face of proximal head **3054**. Washer **3082** may also include a plurality of external threads **3086** for securing housing **3090** thereon.

Housing **3090** may include a generally cylindrical structure defining a lumen **3092** therethrough. Lumen **3092** may include any suitable configuration known in the art. For example, lumen **3092** may include a generally circular cross-sectional configuration. However, any suitable cross-sectional configuration may be used within the principles of the present disclosure. In embodiments where lumen **3092** includes a circular cross-sectional configuration, lumen **3092** may include a generally constant diameter throughout its length or a diameter that varies over the length of lumen **3092**. For example, a proximal portion of lumen **3092** may include a counter bore and therefore may include a larger diameter than a remainder of lumen **3092**. A proximal portion of lumen **3092** may also include screw threads **3093** for threadingly engaging threads **3086** of washer **3082** to retain housing **3090** thereon. Threads **3093** may extend along any suitable portion of lumen **3092**. Walls of lumen **3092** may include one or more grooves **3094**, which may correspond to grooves **3080** and be configured to receive rods **3081**. Rods **3081**, grooves **3094**, and grooves **3080** cooperate to prevent sleeve **3076** from rotating within housing **3090**. Further, housing **3090** may be made of any suitable biocompatible material known in the art, including, for example, PEEK.

Externally, housing **3090** may include any suitable configuration known in the art. In the depicted embodiment, housing **3090** may include a raised proximal portion **3095**. Proximal portion **3095** may include any suitable configuration. In one embodiment, proximal portion **3095** may include a hexagonal configuration (e.g., a hexagonal cross-sectional configuration) for being engaged by an appropriately configured tool. Similarly, proximal portion **3095** may include one or more geometric features **3096** configured to assist with retaining a tool (discussed below) on proximal portion **3095**. The geometric features **3096** may include a plurality of indentations, bumps, recesses, channels, etc. Housing **3090** may further include a raised distal portion **3097**. Raised distal portion **3097** may define a channel **3098** through housing **3090**. Channel **3098** may include any suitable configuration. For example, in one embodiment, channel **3098** may extend in a direction that is substantially perpendicular to a longitudinal axis of lumen **3092**. Channel **3098** may be configured to receive catch **3100** slidably therein. Further, raised distal

19

portion 3097 may include one or more openings 3099 for receiving fasteners 3099a therein. In embodiments where fasteners 3099 include threaded fasteners such as, e.g., screws, openings 3099 may include corresponding threads.

Catch 3100 may include any suitable configuration, and may be dimensioned and shaped to be received within channel 3098. Catch 3100 may be made of any suitable material known in the art, including, e.g., PEEK. In one embodiment, catch 3100 may include a substantially rectangular configuration. As shown in FIG. 31C, lateral surfaces 3102 of catch 3100 may be radiused or curved so that an outer profile of catch 3100 may correspond to raised distal portion 3097 when catch 3100 is received within channel 3098. Further, superior 3104 and/or inferior surfaces of catch 3100 may include one or more openings corresponding to openings 3099. As shown in FIG. 32C, opening 3104 may include any suitable configuration. For example, opening 3104 may include a substantially elongate configuration, whereby fastener 3099a may be slidably disposed in opening 3104. Consequently, catch 3100 may be configured to slide back and forth relative to channel 3098 without becoming disengaged when fasteners 3099 are disposed in openings 3104. Moreover, catch 3100 may define a passageway 3106 therethrough for receiving flange 3027 (at the proximal end of the inserter fork shown in FIG. 31) and/or distal portion 3052a there-through. Passageway 3106 may include any suitable configuration known in the art. In one embodiment, a wall of passageway 3106 may define a circumferential channel 3108 (shown in FIG. 32B) configured to engage flange 3027. The circumferential channel 3108 may be disposed completely around passageway 3106 or only partially around passageway 3106.

With reference now to FIGS. 34-44 a method of operating tool 3000 and its various components to implant an exemplary embodiment of spacer 2700 will be described. As shown in FIG. 34, sleeve 3030 may be advanced distally to squeeze arms 3018, 3020 towards one another so that projections 3024 may engage features 2706 to secure spacer 2700 to tool 3000. Sleeve 3030 may be moved distally by rotating knob 3038 relative to elongate structure 3012. As a result of the coupling via threads 3044 and 3029, rotating knob 3038 relative to elongate structure 3012 may result in knob 3038 and sleeve 3030 moving longitudinally relative to elongate structure 3012.

Once the spacer 2700 is secured to tool 3000, the spacer 2700 may be ready for implantation within a patient. As discussed above, spacer 2700 may be delivered to the inter-body disc space within a patient via any suitable procedure known in the art. For example, in one embodiment, the spacer is delivered via an anterior approach. In another embodiment, the spacer may be delivered via a posterior approach. Further, the approach angle may be any suitable angle known in the art. For example, the spacer 2700 may be delivered by tool 3000 inserted via a posterior approach at an angle of 20-40 degrees offset from a center line of a patient.

Once spacer 2700 is secured to the distal end of the inserter fork, a threaded shaft 3200 may be inserted into a proximal end of actuator assembly 3050 and all the way through the distal end of sleeve 3030 into lumen 2705 of proximal portion 2702 and threaded into lumen 2744 of distal component 2740 of spacer 2700. With reference to FIG. 35, threaded shaft 3200 may include any suitable configuration. In one embodiment, threaded shaft 3200 may include an elongate member 3202. Elongate member 3202 may include any suitable configuration. In embodiment, elongate member 3202 may include a generally cylindrical configuration. For example, elongate member 3202 may include a generally circular

20

cross-sectional configuration. Further, elongate member 3202 may be configured to gradually taper toward its distal end. That is, a proximal portion of elongate member 3202 may include a diameter that is relative larger than a distal portion of elongate member 3202.

In one embodiment, a distal portion, e.g., a distal end, of elongate member 3202 may be configured to engage distal component 2740 of spacer 2700. For example, a distal portion of elongate member 3202 may include one or more geometric configurations configured to cooperate with geometric configurations disposed within lumen 2744 of distal component 2740. In embodiments where lumen 2744 may include threads, for example, a distal portion of elongate member 3202 may also include threads 3208.

A proximal end of elongate member 3202 may include an actuating member 3204. Actuating member 3204 may include any suitable configuration known in the art. In one embodiment, actuating member 3204 may be removably coupled to a proximal portion of elongate member 3202. In another embodiment, actuating member 3204 may be integrally formed with elongate member 3202. Actuating member 3204 may include a knob or a handle in some embodiments. Accordingly, actuating member 3204 may include one or more geometric configurations 3210 to facilitate gripping by an operator. Geometric configurations 3210 may include ridges, channels, protrusions, projections, dents, bumps, recesses, surface texturing, etc. Further, elongate member 3202 may include a channel 3206. Channel 3206 may be disposed at any suitable position along elongate member 3202. In one embodiment, channel 3206 may be disposed closer to a proximal end of elongate member 3202 than a distal end. Channel 3206 may be defined by a portion of elongate member 3202 including a relatively smaller diameter than immediately adjacent portions of elongate member 3202. Channel 3206 may be positioned at a location on elongate member 3202 suitable for being engaged by passageway 3062a (shown in FIG. 32C). Further, actuating member 3204 may include one or more markings 3212 (shown in FIG. 38A) for indicating a degree of expansion of spacer 2700, as described further below. The markings 3212 may include any suitable markings known in the art and may include numerical values corresponding to a percentage of expansion of spacer 2700.

Turning now to FIG. 36, tool 3000 may be secured to spacer 2700 and threaded shaft 3200 may be received within tool 3000. Tool 3000 may be then inserted into a patient to effect implantation of spacer 2700 within the patient. In some embodiments, however, tool 3000 and spacer 2700 may be already positioned within a patient when threaded shaft 3200 is inserted into tool 3000 and secured to spacer 2700.

Turning now to FIG. 37, an expanding hex cap 3700 may be positioned over a proximal end of tool 3000 and actuating member 3204. In one embodiment, hex cap 3700 may include a generally cylindrical member defining a lumen 3702 therein. Lumen 3702 may extend completely through hex cap 3700 or may be blind, such that hex cap 3700 includes a closed proximal end. A distal end portion 3704 of hex cap 3700 may be configured to be received over and engage proximal portion 3095. Accordingly, distal end portion 3704 may include a configuration that corresponds to proximal portion 3095. For example, distal end portion 3704 may be shaped as a hexagonal tool. Further, an inner surface of lumen 3702 in distal portion 3704 may include one or more geometric features 3706 configured to engage geometric features 3096 on proximal portion 3095. In one embodiment, geometric features 3706 may include a plurality of bumps while geometric features 3096 may include a plurality of recesses,

21

or vice versa. In addition, as depicted in FIG. 37, distal end portion 3704 may include a diameter relatively larger than a proximal portion 3708 of hex cap 3700

Further, a proximal portion 3708 of hex cap 3700 may include a plurality of windows or openings 3710 disposed radially thereabout. The openings 3710 may include any suitable configuration known in the art and may facilitate visualizing the markings 3212 disposed on actuating member 3204. Proximal portion 3708 may include any suitable number of openings desired.

In operation, and while spacer 2700 is appropriately positioned (e.g., by moving hex cap 3700 in the direction of arrow 3712) within a patient, hex cap 3700 may be positioned over a proximal end of tool 3000 so that distal end portion 3704 may engage proximal portion 3095 of actuator assembly and actuating member 3204 may be visible to an operator through openings 3710. Next, the operator may rotate hex cap 3700 to expand spacer 2700 until the desired amount of expansion is achieved. Rotating hex cap 3700 causes proximal portion 3095 (and, consequently, housing 3090) to be rotated via its engagement with distal end portion 3704. As a result of the various components and their connections of actuator assembly 3050 described above, when housing 3090 is rotating, sleeve 3076 is also rotated because it is fixed relative to housing 3090 via rods 3081. Consequently, sleeve 3076 and housing 3090 are translated longitudinally relative to central portion 3052. Further, because a proximal end flange 3027 is secured to housing 3090 via catch 3100, the entire inserter fork also translates longitudinally relative to central portion 3052 when hex cap 3700 is rotated. And, since threaded shaft 3200 is secured to central portion 3052 via catch 3206 and tab 3062, the distal threads 3208 threaded into distal component of spacer 2700 may move relative to proximal portion 2702 of spacer 2700 as the inserter fork is moved when hex cap 3700 is rotated. Such relative movement between the distal end of the inserter fork and the threaded shaft 3200 causes proximal portion 2702 to move towards distal component 2740, thereby effecting expansion of spacer 2700 as the various components of spacer are rotated from the positions depicted in FIG. 27B to the positions depicted in FIG. 27A or any suitable, desired intermediate position. As alluded to above, a degree of travel of, e.g., housing 3090 relative to actuating member 3054 may correspond to a degree of expansion of spacer 2700. Accordingly, actuating member 3054 may include a plurality of markings to assist an operator in determining a degree of expansion of spacer 2700.

After desired expansion of spacer 2700 is achieved and spacer 2700 is appropriately positioned within the patient, hex cap 3700 may be removed. Subsequently, tab 3062 may be actuated (e.g., depressed) so that it may temporarily be disengaged from channel 3206 and threaded shaft 3200 may be also removed from tool 3000. In the meantime, position retaining features 2721 and 2727 may interfere with one another to frictionally retain an expanded configuration of spacer 2700. Subsequently, a locking instrument 3900 may be inserted into lumen 3058 and advanced through tool 3000 until it engages within locking feature 2760.

Locking instrument 3900 (see FIG. 39) may include a generally elongate member 3902 having a distal portion 3904 including one or more geometric configurations 3906 configured to engage with geometric configurations 2762a in such a manner that when locking instrument 3900 is rotated, locking feature 2760 will be rotated. As its proximal end, locking instrument may include a suitable actuating member, such as, e.g., a handle or knob 3908. Handle or knob 3908 may be secured to elongate member 3902 by any suitable means known in the art. In one embodiment, handle or knob 3908

22

may be removably coupled to elongate member 3902. In other embodiments, handle or knob 3908 may be integrally formed with elongate member 3902. In some embodiments, locking instrument 3900 may be a torque limiting tool. That is, locking instrument 3900 may be configured to prevent application of torque above a predetermined limit. For example, once a predetermined limit of applied torque is exceeded, handle or knob 3908 may rotate freely relative to elongate member 3902. Handle or knob 3908 may include any suitable configuration known in the art to facilitate gripping and operation by a user. In one embodiment, handle or knob 3908 may include one or more geometric features 3909 (e.g., detents, recesses, protrusions, etc.) configured to allow manipulation by a user.

In operation, distal portion 3904 may be inserted into lumen 2762 so as to engage geometric configurations 2762a, as shown in FIG. 40. Next, handle or knob 3908 may be rotated to advance locking feature 2760 into space 2708 to prevent links 2710 from returning to their collapsed position, thereby locking spacer 2700 in the expanded configuration.

Next, locking instrument 3900 may be removed from tool 3000 and a funnel tube 4100 (see FIG. 41) having a funnel 4200 removably coupled thereto may be inserted into tool 3000 via lumen 3058. Funnel tube 4100 may include any suitable configuration known in the art. In one embodiment, funnel tube 4100 may include an elongate member 4102 defining a lumen 4104 therethrough. Elongate member 4102 may include any suitable configuration. For example, elongate member 4102 may include a generally circular cross-sectional configuration. In some embodiments, however, other cross-sectional configurations, such as, e.g., rectangular, may be used. Similarly, lumen 4104 may include a substantially circular cross-sectional configuration, but any suitable configuration may be employed within the principles of the present disclosure. Elongate member 4102 may have a length sufficient to extend from outside a proximalmost end of tool 3000 to beyond a distal end of locking feature 2760, so as to deliver material into a center of spacer 2700 when it is in the expanded configuration, as discussed below in greater detail.

A proximal end portion 4106 of elongate member 4102 may be configured to be removably secured within lumen 3058. More particularly, proximal end portion 4106 may include threads 4108 configured to engage threads 3064 in proximal head 3054 so as to retain funnel tube 4100 therein. Funnel tube 4100 may further include a knob 4110 disposed proximally of threads 4108. In some embodiments, knob 4110 may include a diameter that is relatively larger than a diameter of a remainder of funnel tube 4100. In addition, knob 4110 may define a lumen (not shown) therethrough. In some embodiments, the lumen of knob 4110 may include a diameter that is relatively larger than a diameter of the lumen 4104 through a remainder of funnel tube 4100. Knob 4110 may also include a plurality of geometric configurations 4112 located on an external surface thereof. The geometric configurations 4112 may include any suitable configuration known in the art. In one embodiment, the geometric configurations may include a plurality of raised ridges, bumps, notches, recesses, detents, etc.

Funnel 4200 may be any suitable funnel known in the art. For example, funnel 4200 may include a conical portion 4202 having a tapering cavity therein. The conical portion 4202 may be secured to or integrally formed with a neck portion 4204 having a lumen defined therethrough. The lumen in neck portion 4204 may be in communication with conical portion 4202. Neck portion 4204 may be removably secured to proximal end portion 4106 by any suitable means known in the art.

23

In one example, neck portion **4204** may include threads configured to matingly engage corresponding threads **4113** (shown in FIG. **43**) disposed on proximal end portion **4106**. In one embodiment, a portion of proximal end portion may be received within neck portion **4204**. In another embodiment, a portion of neck portion **4204** may be received within proximal end portion **4106**.

In use, funnel tube **4100** may be advanced into lumen **3058** and secured therein by engaging threads **4108** with threads **3064**, such that a distal opening of lumen **4104** is disposed through locking feature **2760** within spacer **2700**, as shown in FIG. **42**. Next, the space within spacer **2700** may be filled with morcellated bone (e.g., autograft) or any other suitable material into the center of spacer **2700** when it is in the expanded position. Subsequently, funnel **4200** may be decoupled from funnel tube **4100** by, e.g., unscrewing it. Next, a bone funnel pusher **4300** may be inserted through funnel tube **4100** to push or advance any morcellated bone graft or other material remaining in funnel tube **4100** out of funnel tube **4100** and into a center of spacer **2700**.

As shown in FIG. **43**, bone funnel pusher **4300** may include a generally elongate member **4302** having a proximal end **4304** and a distal end **4306**. Pusher **4300** may include any suitable configuration known in the art. Elongate member **4302** may include any suitable configuration known in the art. For example, elongate member **4302** may include a generally circular cross-sectional configuration. However, elongate member **4302** may include any suitable configuration known in the art. In one embodiment, pusher **4300** may be sized to be advanced through tool **3000** to spacer **2700**. At its proximal end **4304**, pusher **4300** may include a handle **4305**. Handle **4305** may include any suitable configuration. For example, handle **4305** may include a generally tubular structure. Handle **4305** may include a diameter that is relatively larger than a diameter of elongate member **4302**. At its distal end **4306**, elongate member may include a pushing member **4307**. Pushing member **4307** may include any suitable configuration. For example, pushing member **4307** may be substantially tubular. In one embodiment, pushing member **4307** may include a diameter that is relatively larger than a diameter of elongate member **4302**, but relatively smaller than a diameter of handle **4305**.

In use, the bone funnel pusher **4300** may be used to fill spacer **2700** with, e.g., finely milled autogenous bone graft material to tightly pack spacer **2700**. Once the graft material is tightly packed within spacer **2700**, the inserter knob **3038** may be rotated to withdraw sleeve **3030** to disengage the inserter fork from spacer **2700**. Prior to final disengagement, however, a user may choose to verify a final positioning of the spacer **2700** via radiographic visualization, such as, e.g., fluoroscopy, X-ray, or any other suitable imaging technique, as shown in FIG. **44**.

If necessary, the spacer **2700** may be removed or otherwise manipulated by first inserting a removal tool (not shown) through a distal end of lumen **2744** in distal component **2740**. The removal tool may engage locking feature **2760** and advance it completely back into cylindrical portion **2703** of proximal portion **2702**, thereby removing the impediment to links **2710** and **2712** returning to their collapsed position. Next, projections **3024** of arms **3018**, **3020** may engage features **2706** as described above. Threaded shaft **3200** may then be inserted through tool **3000** to engage threads **3208** within distal component **2740**. Subsequently, hex cap **3700** may be provided over a proximal end of tool **3000** for rotation so as to collapse **2700** for removal from within the patient.

As described above, the devices, tools, and methods described herein may be used to provide an interbody spacer

24

for positioning between adjacent vertebral bodies. Prior to performing the above-described steps, those of ordinary skill in the art will understand that a patient's native intervertebral disc may be first removed via a conventional discectomy, for example. Alternatively, scrapers may be used for disc distractions and to loosen the disc space without damaging vertebral endplates. In one embodiment, an operator may begin distraction with a relatively small scraper and proceed with increasingly larger scrapers. Next, the disc space may be prepared for receiving, for example, spacer **2700** as known in the art. Subsequently, measurements may be made of a height and width of the interbody disc space to ensure a spacer of correct dimensions is selected for implantation. The measurements may be made by any suitable means known in the art. For example, a user may conduct one or more adjustable footprint trials. In particular, one or more trials may be inserted into the prepared disc space in a collapsed configuration and expanded. The trial may be observed under suitable imaging means, such as, e.g., fluoroscopy, to identify appropriate sizing suitable for the prepared disc space.

While the invention herein disclosed has been described by means of specific embodiments and applications thereof, numerous modifications and variations can be made thereto by those skilled in the art without departing from the scope of the invention as set forth in the claims.

What is claimed is:

1. A system for treating a vertebral condition, the system comprising:

an interbody implant configured to transition between a first configuration and a second configuration, wherein the interbody implant comprises:

a first arm including a first end and a second end, wherein the first arm is defined by a plurality of links coupled to one another;

a second arm including a first end and a second end, wherein the second arm is defined by a plurality of links coupled to one another;

a proximal component coupled to the first ends of the first and second arms, wherein the proximal component includes a lumen with threads;

a distal component coupled to the second ends of the first and second arms; and

a locking feature received in the lumen, wherein the locking feature includes threads that engage the threads of the lumen;

an insertion tool for positioning the implant within a patient, the insertion tool comprising:

an elongate member defining a distal end and a lumen extending therethrough, wherein the elongate member is configured to releasably engage the proximal component of the interbody implant; and

a shaft member disposed within the lumen of the elongate member and configured to releasably engage the distal component, wherein actuation of the insertion tool moves the elongate member relative to shaft member to transition the implant between first configuration and the second configuration.

2. The system of claim 1, wherein the first configuration is a collapsed configuration and the second configuration is an expanded configuration.

3. The system of claim 1, wherein one or both of the proximal and distal components includes a passageway there-through.

4. The system of claim 1, wherein the plurality of links defining the first arm are configured to engage each other to maintain a position of a first link of the plurality of links relative to another link of the plurality of links.

25

5. The system of claim 1, further comprising a locking mechanism for preventing the implant from returning to the second configuration from the first configuration when the locking mechanism is activated.

6. The system of claim 1, wherein the distal end of the elongate member includes a plurality of resilient arms.

7. The system of claim 6, further comprising a sleeve slidably disposed over the elongate member, wherein the sleeve is configured to urge at least one of the plurality of resilient arms towards the other of the plurality of resilient arms.

8. A method of positioning an interbody implant in a space between adjacent vertebral bodies, the method comprising:

positioning the interbody implant within the space, wherein the interbody implant comprises:

a first arm including a first end and a second end, wherein the first arm is defined by a plurality of links rotatably coupled to one another;

a second arm including a first end and a second end, wherein the second arm is defined by a plurality of links rotatably coupled to one another;

a proximal component coupled to the first ends of the first and second arms, wherein the proximal component includes a lumen with threads; and

a distal component coupled to the second ends of the first and second arms;

transitioning the interbody implant from a first configuration to a second configuration; and

activating a locking mechanism to maintain the interbody implant in the second configuration, wherein the locking mechanism includes threads that engage the threads of the lumen.

9. The method of claim 8, further comprising removing a native disc and preparing the space prior to inserting the expandable interbody implant.

10. The method of claim 9, further comprising measuring at least one of a height and a width dimension of the space.

11. The method of claim 9, wherein positioning the interbody implant within the space includes advancing the interbody implant to the space via a posterior approach.

26

12. The method of claim 8, wherein, in the second configuration, the interbody implant encloses a region defined by the first arm, the second arm, the proximal component, and the distal component.

13. The method of claim 12, further comprising delivering a material to the region via an elongate tool.

14. The method of claim 8, wherein the plurality of links defining the first arm are configured to engage each other to maintain a position of a first link of the plurality of links relative to another link of the plurality of links.

15. The method of claim 8, further comprising visualizing the implant via fluoroscopy.

16. A method of positioning an interbody implant in a space between adjacent vertebral bodies, the method comprising:

positioning the interbody implant within the space, wherein the interbody implant comprises:

a first arm including a first end and a second end, wherein the first arm is defined by at least one link member;

a second arm including a first end and a second end, wherein the second arm is defined by at least one link member;

a proximal component coupled to the first arm, wherein the proximal component comprises a lumen with threads; and

transitioning the interbody implant from a first configuration to a second configuration; and

activating a locking mechanism to maintain the interbody implant in the second configuration, wherein the locking mechanism includes threads that engage the threads of the lumen.

17. The method of claim 16, wherein the second arm comprises at least two link members.

18. The method of claim 17, wherein the at least two link members of the second arm comprises a first link and a second link connected to one another via a pin member.

19. The method of claim 17, wherein the interbody implant is positioned within the space via a lateral approach.

20. The method of claim 17, wherein the interbody implant includes at least one window disposed radially about the implant.
